

Basic Structure

- Formally, given sets D_1 , D_2 , D_n a relation r is a subset of $D_1 \times D_2 \times ... \times D_n$ Thus a relation is a set of n-tuples $(a_1, a_2, ..., a_n)$ where $a_i \in D_i$
- Example: if

is a relation over customer-name x customer-street x customer-city

Database System Concepts

3.3

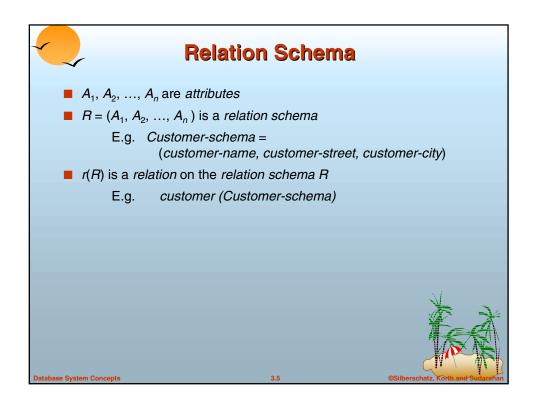

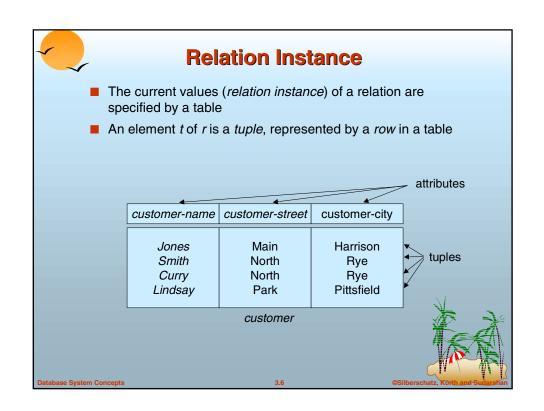

Attribute Types

- Each attribute of a relation has a name
- The set of allowed values for each attribute is called the domain of the attribute
- Attribute values are (normally) required to be atomic, that is, indivisible
 - ★ E.g. multivalued attribute values are not atomic
 - ★ E.g. composite attribute values are not atomic
- The special value *null* is a member of every domain
- The null value causes complications in the definition of many operations
 - ★ we shall ignore the effect of null values in our main presentation and consider their effect later

atabase System Concepts

Relations are Unordered

- Order of tuples is irrelevant (tuples may be stored in an arbitrary order)
- E.g. *account* relation with unordered tuples

account-number	branch-name	balance
A-101	Downtown	500
A-215	Mianus	700
A-102	Perryridge	400
A-305	Round Hill	350
A-201	Brighton	900
A-222	Redwood	700
A-217	Brighton	<i>7</i> 50

Database System Concepts

27

Database

- A database consists of multiple relations
- Information about an enterprise is broken up into parts, with each relation storing one part of the information

E.g.: account: stores information about accounts

depositor: stores information about which customer

owns which account

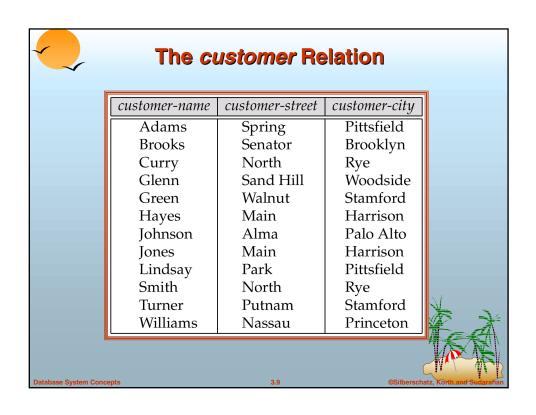

customer: stores information about customers

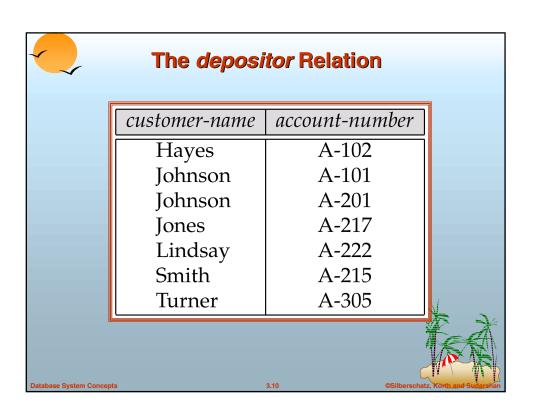

- Storing all information as a single relation such as bank(account-number, balance, customer-name, ..) results in
 - ★ repetition of information (e.g. two customers own an account)
 - the need for null values (e.g. represent a customer without an account)
- Normalization theory (Chapter 7) deals with how to design relational schemas

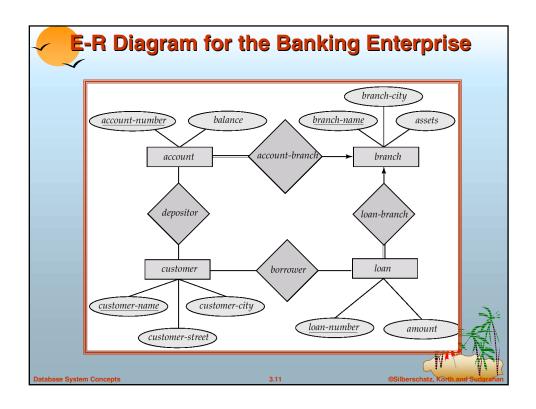

atabase System Concents

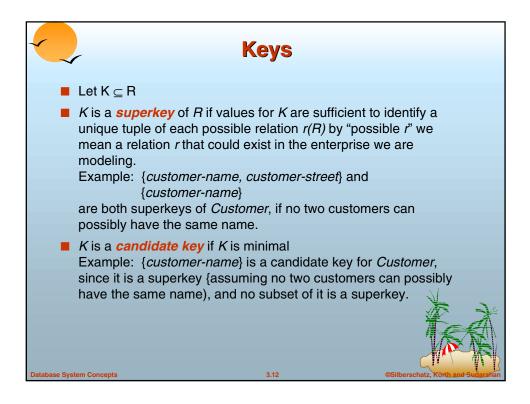

3.8

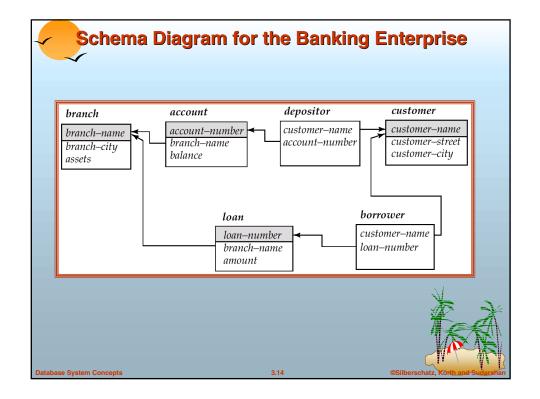

Determining Keys from E-R Sets

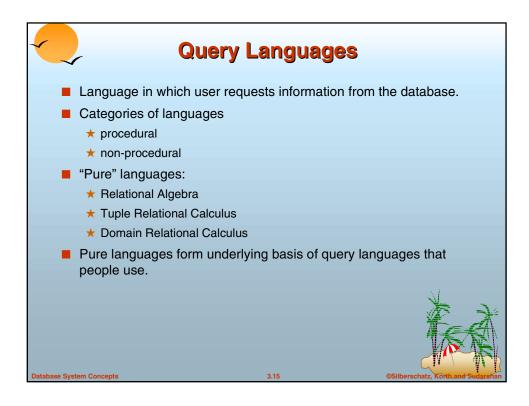

- **Strong entity set**. The primary key of the entity set becomes the primary key of the relation.
- Weak entity set. The primary key of the relation consists of the union of the primary key of the strong entity set and the discriminator of the weak entity set.
- Relationship set. The union of the primary keys of the related entity sets becomes a super key of the relation.
 - ★ For binary many-to-one relationship sets, the primary key of the "many" entity set becomes the relation's primary key.
 - ★ For one-to-one relationship sets, the relation's primary key can be that of either entity set.
 - ★ For many-to-many relationship sets, the union of the primary keys becomes the relation's primary key

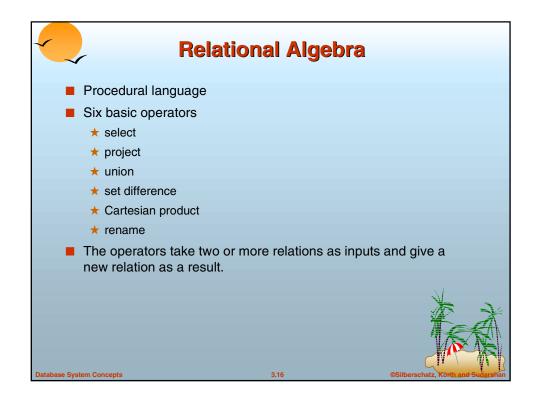

Database System Concepts

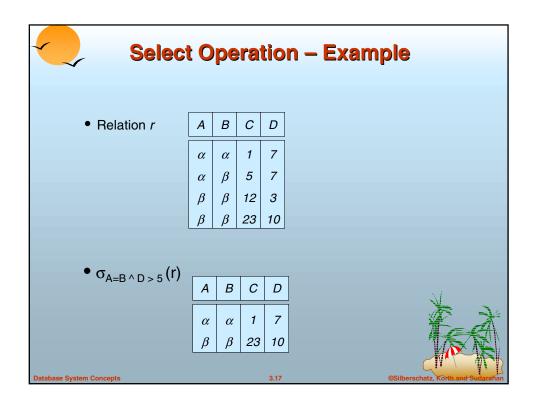

3.13

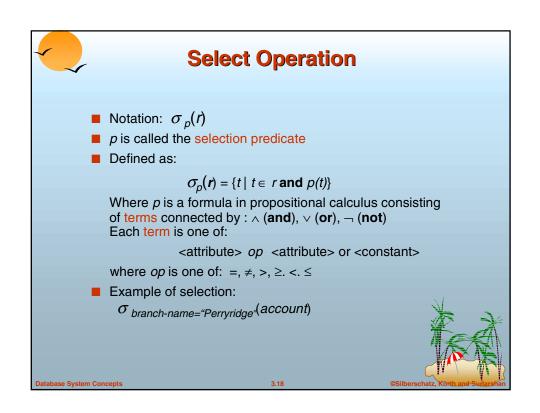

Silverschalz, Korulana Sugasma

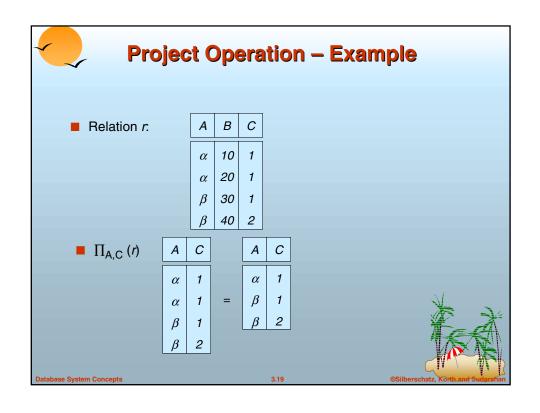

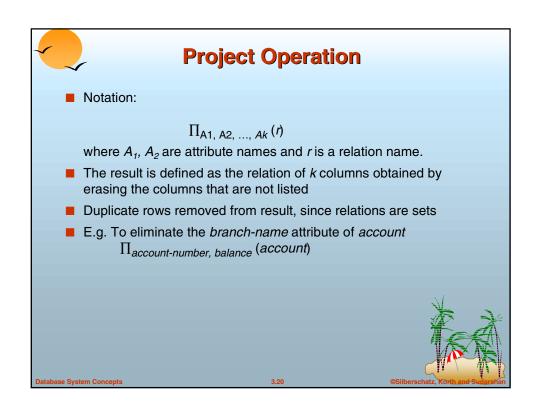

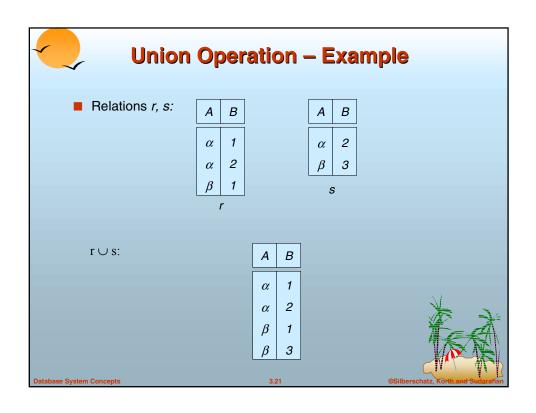

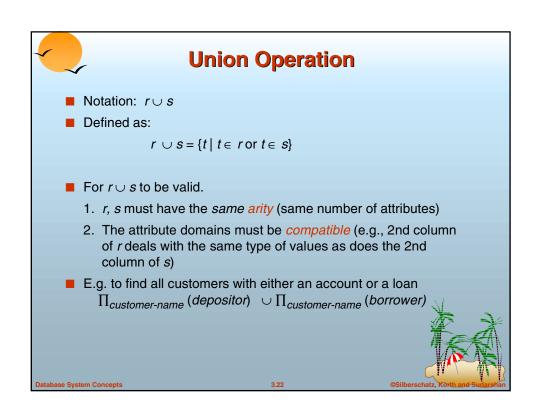

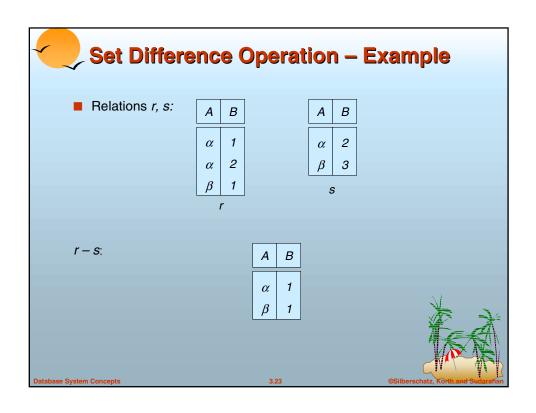

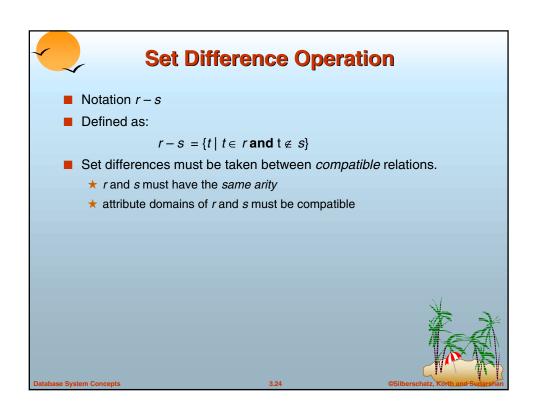

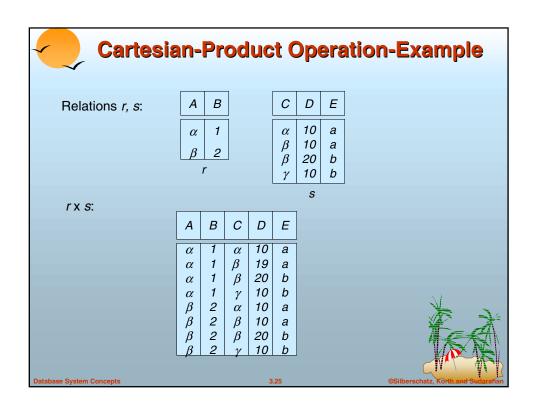

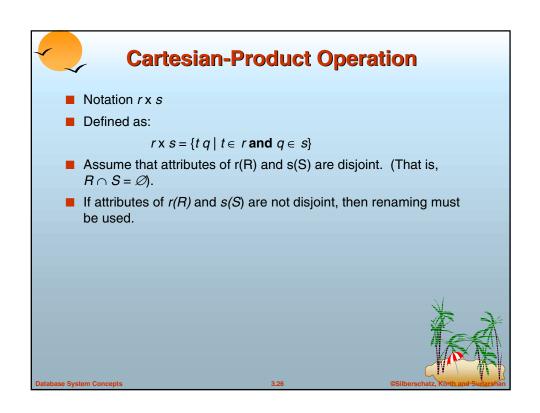

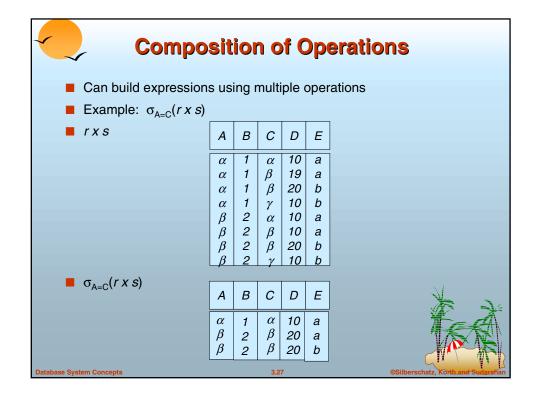

Rename Operation

- Allows us to name, and therefore to refer to, the results of relational-algebra expressions.
- Allows us to refer to a relation by more than one name.

Example:

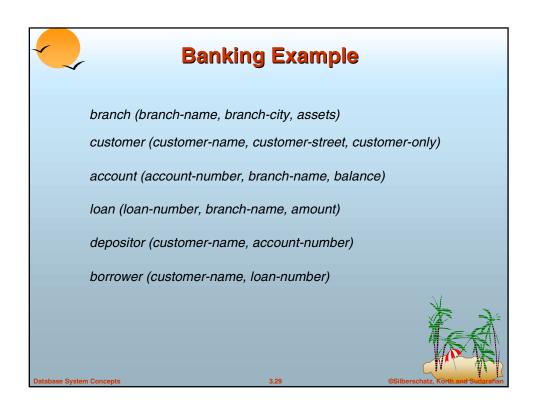

$$\rho_X(E)$$

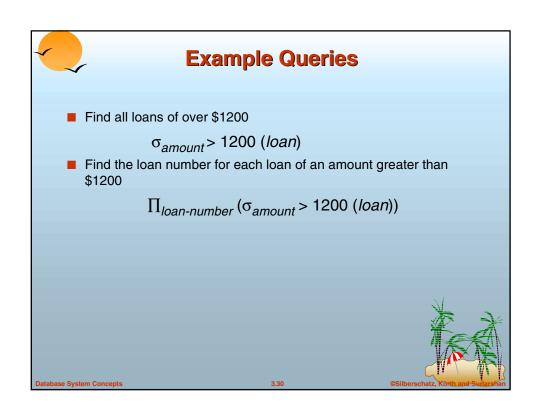

returns the expression E under the name X If a relational-algebra expression E has arity n, then

$$\rho_{X (A1, A2, ..., An)}(E)$$

returns the result of expression *E* under the name *X*, and with the attributes renamed to *A1*, *A2*,, *An*.

Database System Concepts

Example Queries

- Find the names of all customers who have a loan, an account, or both, from the bank
 - $\prod_{customer-name}$ (borrower) $\cup \prod_{customer-name}$ (depositor)
- Find the names of all customers who have a loan and an account at bank.
 - $\Pi_{customer-name}$ (borrower) $\cap \Pi_{customer-name}$ (depositor)

Database System Concept

2 21

Example Queries

- Find the names of all customers who have a loan at the Perryridge branch.
 - $\prod_{customer-name} (\sigma_{branch-name="Perryridge"})$
 - $(\sigma_{borrower.loan-number} = loan.loan-number(borrower x loan)))$
- Find the names of all customers who have a loan at the Perryridge branch but do not have an account at any branch of the bank.
 - $\Pi_{customer-name}$ ($\sigma_{branch-name}$ = "Perryridge"
 - $(\sigma_{borrower.loan-number = loan.loan-number}(borrower x loan)))$
 - Π_{customer-name}(depositor)

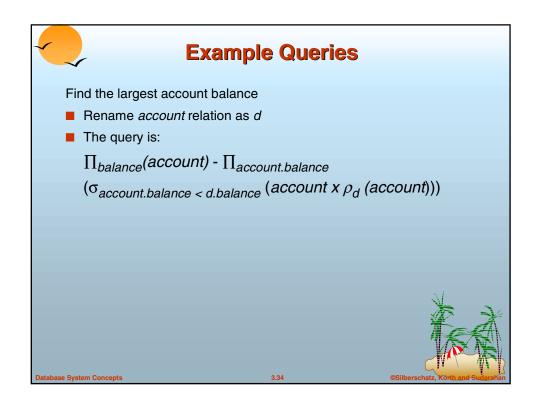

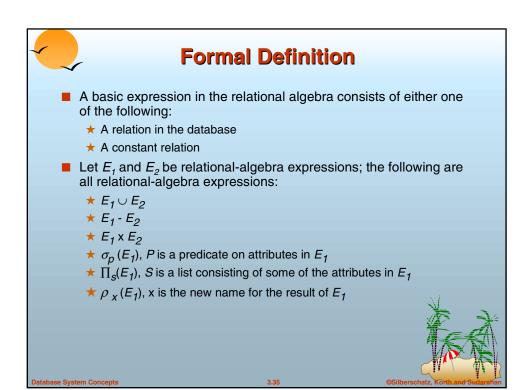

atabase System Concepts

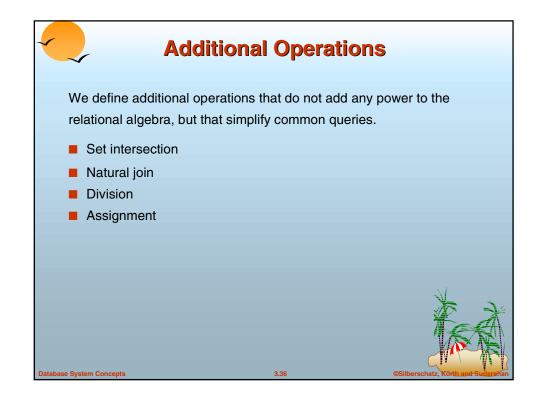

```
Example Queries

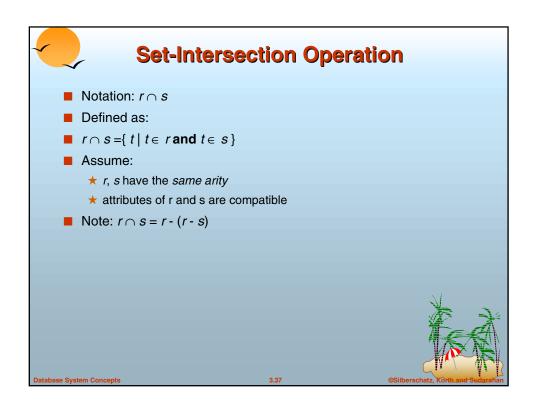

Find the names of all customers who have a loan at the Perryridge branch.

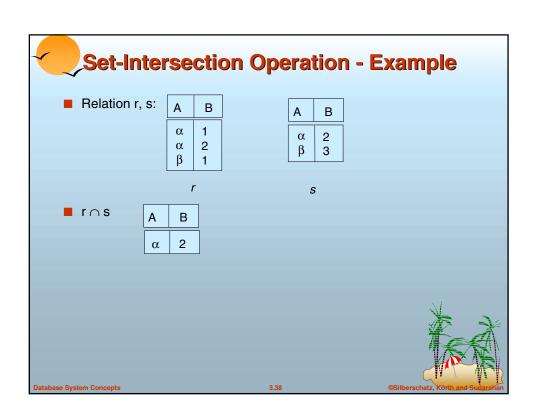

Query 1
Πcustomer-name(σbranch-name = "Perryridge"
(σborrower.loan-number = loan.loan-number(borrower x loan)))
Query 2
Πcustomer-name(σloan.loan-number = borrower.loan-number(σbranch-name = "Perryridge"(loan)) x borrower)
)
```

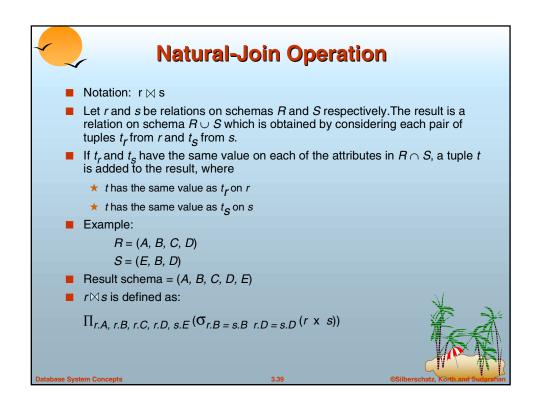

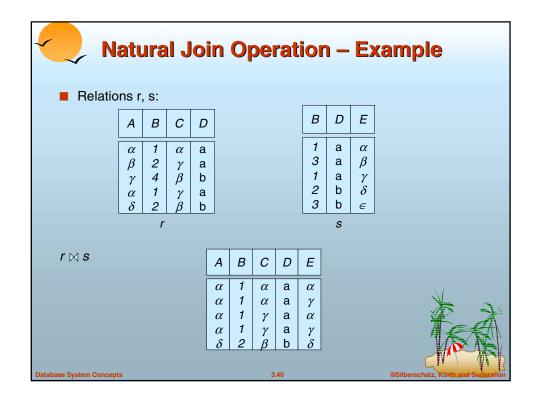

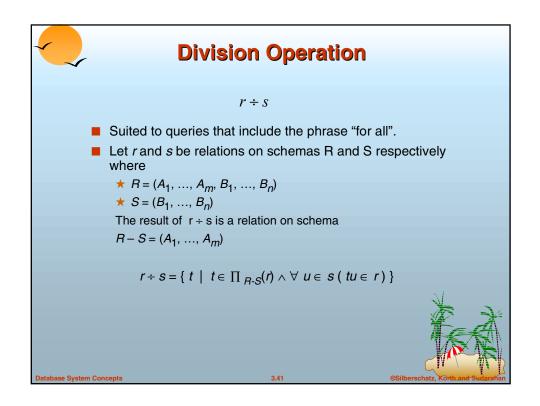

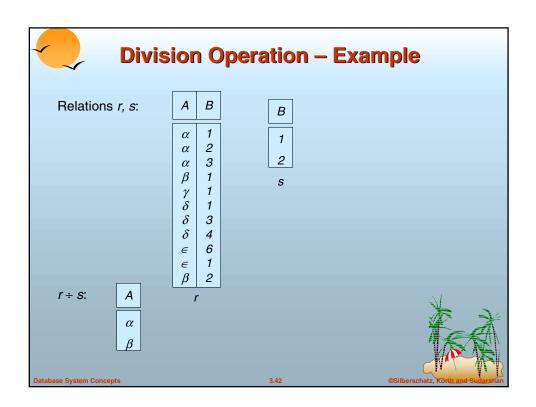

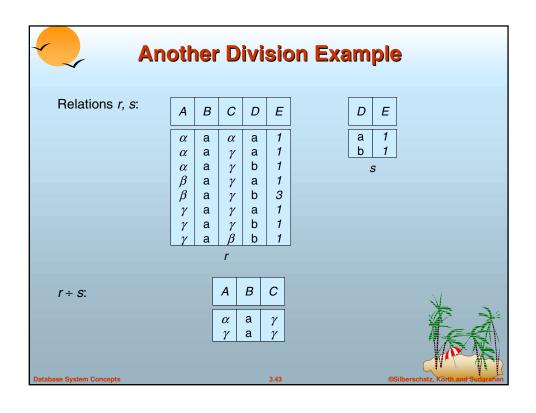

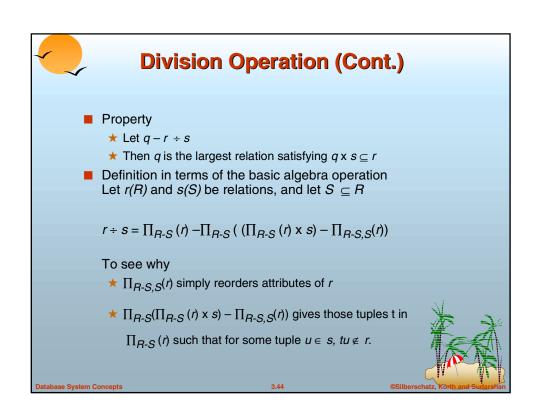

Assignment Operation

- The assignment operation (\leftarrow) provides a convenient way to express complex queries, write query as a sequential program consisting of a series of assignments followed by an expression whose value is displayed as a result of the query.
- Assignment must always be made to a temporary relation variable.
- Example: Write $r \div s$ as

$$\begin{split} temp1 \leftarrow & \prod_{R\text{-}S} (\textit{r}) \\ temp2 \leftarrow & \prod_{R\text{-}S} ((temp1 \text{ x s}) - \prod_{R\text{-}S,S} (\textit{r})) \\ result = temp1 - temp2 \end{split}$$

- \star The result to the right of the \leftarrow is assigned to the relation variable on the left of the \leftarrow .
- ★ May use variable in subsequent expressions.

★ Query 1

 $\Pi_{CN}(\sigma_{BN="Downtown"}(depositor \bowtie account)) \cap$

 $\prod_{\mathit{CN}} (\sigma_{\mathit{BN}=\text{"Uptown"}}(\mathit{depositor} \bowtie \mathit{account}))$

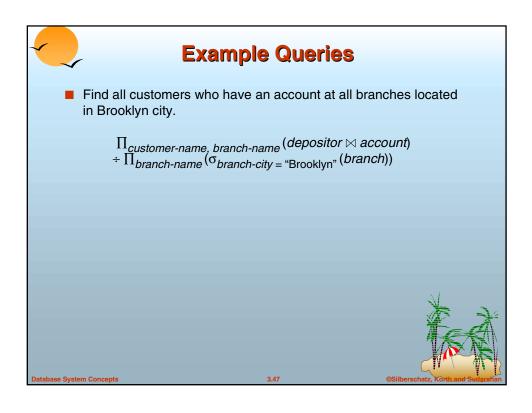

where CN denotes customer-name and BN denotes branch-name.

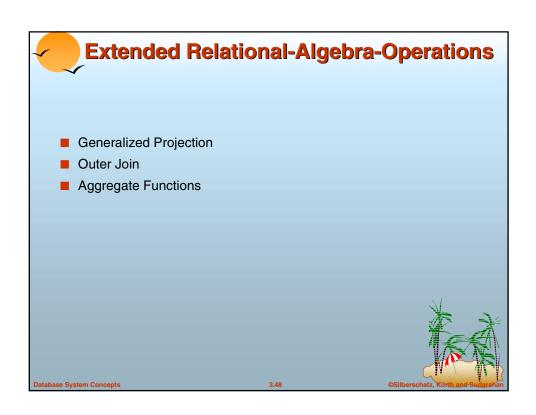

★ Query 2

 $\Pi_{ extit{customer-name, branch-name}}$ (depositoroxtimes account)

÷ $\rho_{\text{temp(branch-name)}}$ ({("Downtown"), ("Uptown")})

Generalized Projection

Extends the projection operation by allowing arithmetic functions to be used in the projection list.

$$\prod_{\mathsf{F1},\mathsf{F2},\ldots,\mathsf{Fn}}(E)$$

- E is any relational-algebra expression
- Each of F_1 , F_2 , ..., F_n are are arithmetic expressions involving constants and attributes in the schema of E.
- Given relation credit-info(customer-name, limit, credit-balance), find how much more each person can spend:

 $\Pi_{customer-name, limit-credit-balance}$ (credit-info)

Database System Concepts

3.49

Aggregate Functions and Operations

Aggregation function takes a collection of values and returns a single value as a result.

avg: average value

min: minimum valuemax: maximum value

sum: sum of values
count: number of values

■ Aggregate operation in relational algebra

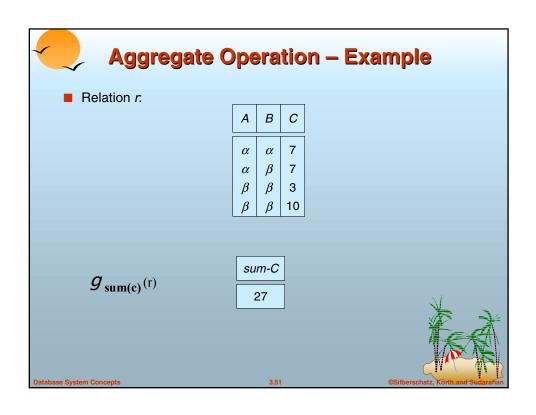

$$g_{1, G2, ..., Gn} g_{F1(A1), F2(A2), ..., Fn(An)}(E)$$

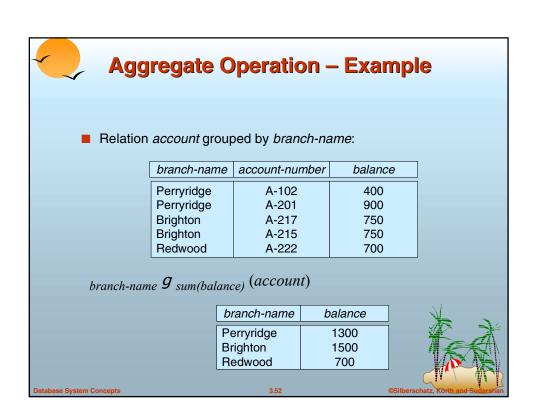

- ★ E is any relational-algebra expression
- $\star G_1, G_2 ..., G_n$ is a list of attributes on which to group (can be empty)
- ★ Each F_i is an aggregate function
- ★ Each A; is an attribute name

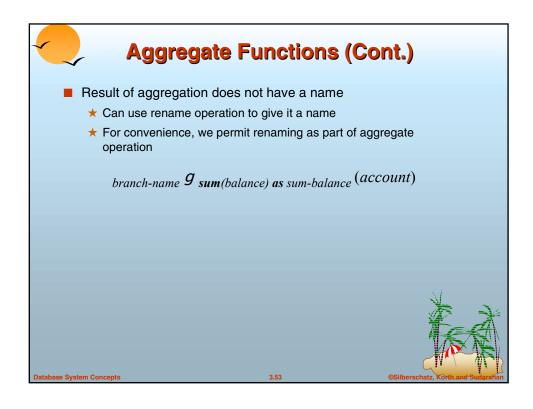

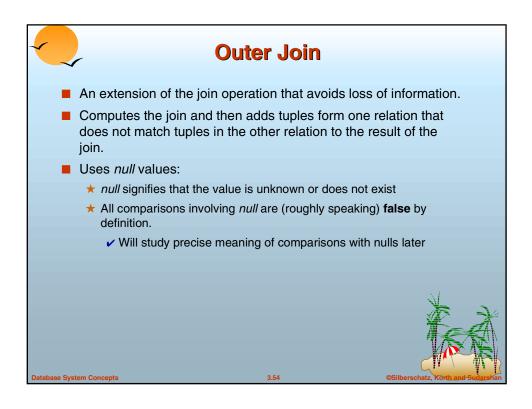

atabase System Concepts

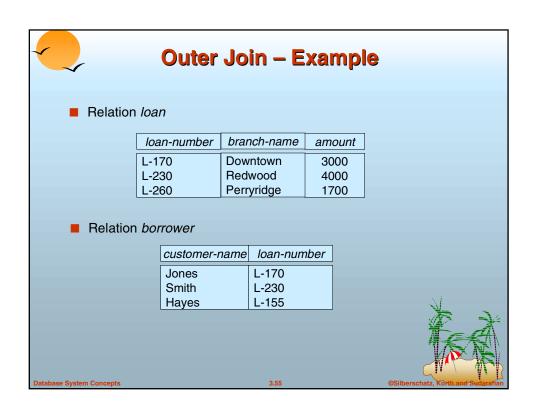

3.50

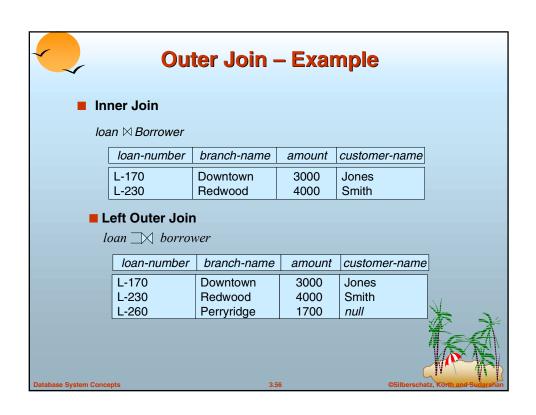

Outer Join - Example

■ Right Outer Join

loan ⋈ borrower

loan-number	branch-name	amount	customer-name
L-170	Downtown	3000	Jones
L-230	Redwood	4000	Smith
L-155	null	null	Hayes

■ Full Outer Join

loan ⇒ *borrower*

loan-number	branch-name	amount	customer-name
L-170	Downtown	3000	Jones
L-230	Redwood	4000	Smith
L-260	Perryridge	1700	null
L-155	null	null	Hayes

Database System Concepts

3.57

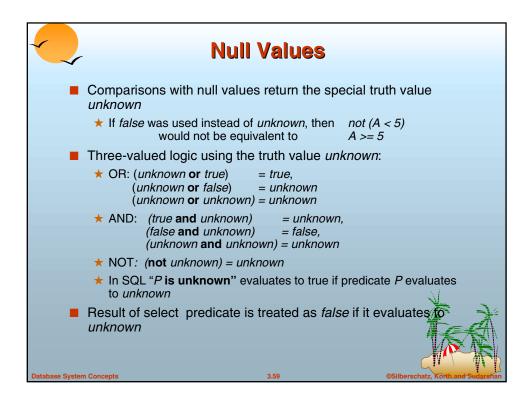

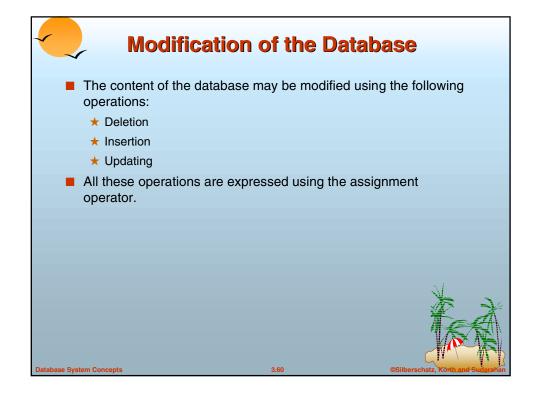

Null Values

- It is possible for tuples to have a null value, denoted by *null*, for some of their attributes
- *null* signifies an unknown value or that a value does not exist.
- The result of any arithmetic expression involving *null* is *null*.
- Aggregate functions simply ignore null values
 - ★ Is an arbitrary decision. Could have returned null as result instead.
 - ★ We follow the semantics of SQL in its handling of null values
- For duplicate elimination and grouping, null is treated like any other value, and two nulls are assumed to be the same
 - ★ Alternative: assume each null is different from each other
 - ★ Both are arbitrary decisions, so we simply follow SQL

atabase System Concepts

Deletion

- A delete request is expressed similarly to a query, except instead of displaying tuples to the user, the selected tuples are removed from the database.
- Can delete only whole tuples; cannot delete values on only particular attributes
- A deletion is expressed in relational algebra by:

$$r \leftarrow r - E$$

where r is a relation and E is a relational algebra query.

Database System Concepts

3.61

Deletion Examples

Delete all account records in the Perryridge branch.

 $account \leftarrow account - \sigma_{branch-name = "Perryridge"}(account)$

■ Delete all loan records with amount in the range of 0 to 50

loan ← loan − σ amount ≥ 0 and amount ≤ 50 (loan)

Delete all accounts at branches located in Needham.

 $r_1 \leftarrow \sigma_{\textit{branch-city}} = \text{``Needham'''} (\textit{account} \underset{\bowtie}{\bowtie} \textit{branch})$

 $\mathbf{r_2} \leftarrow \Pi_{branch\text{-}name, account\text{-}number, balance} (\mathbf{r_1})$

 $r_3 \leftarrow \prod_{customer-name, account-number} (r_2_{\bowtie} depositor)$

 $account \leftarrow account - r_2$

 $depositor \leftarrow depositor - r_3$

Database System Concepts

Insertion

- To insert data into a relation, we either:
 - * specify a tuple to be inserted
 - ★ write a query whose result is a set of tuples to be inserted
- in relational algebra, an insertion is expressed by:

$$r \leftarrow r \cup E$$

where r is a relation and E is a relational algebra expression.

■ The insertion of a single tuple is expressed by letting *E* be a constant relation containing one tuple.

Database System Concepts

3 63

Insertion Examples

Insert information in the database specifying that Smith has \$1200 in account A-973 at the Perryridge branch.

$$account \leftarrow account \cup \{("Perryridge", A-973, 1200)\}$$

depositor $\leftarrow depositor \cup \{("Smith", A-973)\}$

■ Provide as a gift for all loan customers in the Perryridge branch, a \$200 savings account. Let the loan number serve as the account number for the new savings account.

$$r_1 \leftarrow (\sigma_{\textit{branch-name}} = \textit{"Perryridge"} (\textit{borrower} \bowtie \textit{loan}))$$
 $account \leftarrow account \cup \prod_{\textit{branch-name, account-number,200}} (r_1)$ $depositor \leftarrow \textit{depositor} \cup \prod_{\textit{customer-name, loan-number,}} (r_1)$

Database System Concepts

Updating

- A mechanism to change a value in a tuple without charging all values in the tuple
- Use the generalized projection operator to do this task

$$r \leftarrow \prod_{F1, F2, ..., FI,} (r)$$

- Each *F*, is either the *i*th attribute of *r*, if the *i*th attribute is not updated, or, if the attribute is to be updated
- \blacksquare F_i is an expression, involving only constants and the attributes of r, which gives the new value for the attribute

Database System Concepts

3.65

Update Examples

- Make interest payments by increasing all balances by 5 percent. account ← ∏ AN, BN, BAL * 1.05 (account)
 - where AN, BN and BAL stand for account-number, branch-name and balance, respectively.
- Pay all accounts with balances over \$10,000
 6 percent interest and pay all others 5 percent

 $\begin{array}{ll} \textit{account} \leftarrow & \prod_{\textit{AN, BN, BAL}} *_{1.06} (\sigma_{\textit{BAL} > 10000} (\textit{account})) \\ & \cup & \prod_{\textit{AN, BN, BAL}} *_{1.05} (\sigma_{\textit{BAL} \leq 10000} (\textit{account})) \end{array}$

atabase System Concepts

Views

- In some cases, it is not desirable for all users to see the entire logical model (i.e., all the actual relations stored in the database.)
- Consider a person who needs to know a customer's loan number but has no need to see the loan amount. This person should see a relation described, in the relational algebra, by

 $\prod_{customer-name,\ loan-number}$ (borrower \Join loan)

Any relation that is not of the conceptual model but is made visible to a user as a "virtual relation" is called a view.

Database System Concepts

3.67

View Definition

A view is defined using the create view statement which has the form

create view v as <query expression</pre>

where <query expression> is any legal relational algebra query expression. The view name is represented by v.

- Once a view is defined, the view name can be used to refer to the virtual relation that the view generates.
- View definition is not the same as creating a new relation by evaluating the query expression Rather, a view definition causes the saving of an expression to be substituted into queries using the view.

Database System Concepts

View Examples

■ Consider the view (named *all-customer*) consisting of branches and their customers.

create view all-customer as

 $\Pi_{\mathit{branch-name}}$, customer-name (depositor \bowtie account)

 $\cup \prod_{\mathit{branch-name}}$ (borrower \bowtie loan)

■ We can find all customers of the Perryridge branch by writing:

 $\Pi_{branch-name}$

(σ_{branch-name =} "Perryridge" (all-customer))

Database System Concepts

3.69

Updates Through View

- Database modifications expressed as views must be translated to modifications of the actual relations in the database.
- Consider the person who needs to see all loan data in the loan relation except amount. The view given to the person, branchloan, is defined as:

create view branch-loan as

 $\Pi_{branch-name, loan-number}$ (loan)

■ Since we allow a view name to appear wherever a relation name is allowed, the person may write:

branch-loan ← branch-loan ∪ {("Perryridge", L-37)}

atabase System Concepts

Updates Through Views (Cont.)

- The previous insertion must be represented by an insertion into the actual relation *loan* from which the view *branch-loan* is constructed.
- An insertion into *loan* requires a value for *amount*. The insertion can be dealt with by either.
 - ★ rejecting the insertion and returning an error message to the user.
 - ★ inserting a tuple ("L-37", "Perryridge", null) into the loan relation
- Some updates through views are impossible to translate into database relation updates
 - ★ create view v as σ_{branch-name = "Perryridge"} (account)) v ← v ∪ (L-99, Downtown, 23)
- Others cannot be translated uniquely
 - ★ all-customer ← all-customer ∪ (Perryridge, John)
 - Have to choose loan or account, and create a new loan/account number!

Database System Concepts

3.71

Views Defined Using Other Views

- One view may be used in the expression defining another view
- A view relation v_1 is said to *depend directly* on a view relation v_2 if v_2 is used in the expression defining v_1
- A view relation v₁ is said to depend on view relation v₂ if either v₁ depends directly to v₂ or there is a path of dependencies from v₁ to v₂
- A view relation *v* is said to be *recursive* if it depends on itself.

Database System Concepts

View Expansion

- A way to define the meaning of views defined in terms of other views.
- Let view v_1 be defined by an expression e_1 that may itself contain uses of view relations.
- View expansion of an expression repeats the following replacement step:

repeat

Find any view relation v_i in e_1 Replace the view relation v_i by the expression defining v_i **until** no more view relations are present in e_1

As long as the view definitions are not recursive, this loop will terminate

Database System Concepts

3.73

Tuple Relational Calculus

■ A nonprocedural query language, where each query is of the form

 $\{t \mid P(t)\}$

- It is the set of all tuples *t* such that predicate *P* is true for *t*
- \blacksquare t is a tuple variable, f[A] denotes the value of tuple t on attribute A
- $t \in r$ denotes that tuple t is in relation r
- *P* is a *formula* similar to that of the predicate calculus

Database System Concepts

Predicate Calculus Formula

- 1. Set of attributes and constants
- 2. Set of comparison operators: (e.g., <, \le , =, \ne , >, \ge)
- 3. Set of connectives: and (\land) , or (\lor) , not (\neg)
- 4. Implication (\Rightarrow): $x \Rightarrow y$, if x if true, then y is true

$$x \Rightarrow y \equiv \neg x \lor y$$

- 5. Set of quantifiers:
 - $\exists t \in r(Q(t)) \equiv$ "there exists" a tuple in t in relation r such that predicate Q(t) is true
 - $\forall t \in r(Q(t)) \equiv Q$ is true "for all" tuples t in relation r

Database System Concepts

3.75

Banking Example

- branch (branch-name, branch-city, assets)
- customer (customer-name, customer-street, customer-city)
- account (account-number, branch-name, balance)
- loan (loan-number, branch-name, amount)
- depositor (customer-name, account-number)
- borrower (customer-name, loan-number)

atabase System Concepts

■ Find the *loan-number, branch-name*, and *amount* for loans of over \$1200

 $\{t \mid t \in loan \land t [amount] > 1200\}$

■ Find the loan number for each loan of an amount greater than \$1200

```
\{t \mid \exists s \in \text{loan } (t[\text{loan-number}] = s[\text{loan-number}] \land s[\text{amounf}] > 1200\}
```

Notice that a relation on schema [customer-name] is implicitly defined by the query

Database System Concepts

3.77

Example Queries

Find the names of all customers having a loan, an account, or both at the bank

 $\{t \mid \exists s \in borrower(t[customer-name] = s[customer-name]) \\ \lor \exists u \in depositor(t[customer-name] = u[customer-name])$

■ Find the names of all customers who have a loan and an account at the bank

 $\{t \mid \exists s \in borrower(t[customer-name] = s[customer-name]) \land \exists u \in depositor(t[customer-name] = u[customer-name])$

atabase System Concepts

■ Find the names of all customers having a loan at the Perryridge branch

■ Find the names of all customers who have a loan at the Perryridge branch, but no account at any branch of the bank

Database System Concepts

3.79

Example Queries

Find the names of all customers having a loan from the Perryridge branch, and the cities they live in

atabase System Concepts

Find the names of all customers who have an account at all branches located in Brooklyn:

```
\{t \mid \exists \ c \in \text{customer} \ (t[\text{customer.name}] = c[\text{customer-name}]) \land \forall \ s \in branch(s[branch-city] = \text{``Brooklyn''} \Rightarrow \exists \ u \in account \ (s[branch-name] = u[branch-name] \land \exists \ s \in depositor \ (t[customer-name] = s[\text{customer-name}] \land s[account-number] = u[\text{account-number}] \ )) \}
```

Database System Concepts

3.81

Safety of Expressions

- It is possible to write tuple calculus expressions that generate infinite relations.
- For example, $\{t \mid \neg t \in r\}$ results in an infinite relation if the domain of any attribute of relation r is infinite
- To guard against the problem, we restrict the set of allowable expressions to safe expressions.
- An expression $\{t \mid P(t)\}$ in the tuple relational calculus is *safe* if every component of *t* appears in one of the relations, tuples, or constants that appear in *P*

atabase System Concepts

Domain Relational Calculus

- A nonprocedural query language equivalent in power to the tuple relational calculus
- Each query is an expression of the form:

$$\{ \langle x_1, x_2, ..., x_n \rangle \mid P(x_1, x_2, ..., x_n) \}$$

- $\star x_1, x_2, ..., x_n$ represent domain variables
- ★ P represents a formula similar to that of the predicate calculus

Database System Concepts

3.83

Example Queries

■ Find the *branch-name*, *loan-number*, and *amount* for loans of over \$1200

$$\{ < l, b, a > | < l, b, a > \in loan \land a > 1200 \}$$

■ Find the names of all customers who have a loan of over \$1200

$$\{ \langle c \rangle \mid \exists l, b, a \ (\langle c, l \rangle \in borrower \land \langle l, b, a \rangle \in loan \land a > 1200) \}$$

Find the names of all customers who have a loan from the Perryridge branch and the loan amount:

$$\{\langle c, a \rangle \mid \exists l \ (\langle c, l \rangle \in borrower \land \exists b (\langle l, b, a \rangle \in loan \land loa$$

b = "Perryridge"))}

or $\{\langle c, a \rangle \mid \exists l \ (\langle c, l \rangle \in borrower \land \langle l, "Perryridge", a \rangle \in A\}$

atabase System Concepts

3.84

Find the names of all customers having a loan, an account, or both at the Perryridge branch:

```
\{ \langle c \rangle \mid \exists \ I (\{ \langle c, I \rangle \in borrower \land \exists \ b, a (\langle I, b, a \rangle \in loan \land b = "Perryridge") \} 
\lor \exists \ a (\langle c, a \rangle \in depositor \land \exists \ b, n (\langle a, b, n \rangle \in account \land b = "Perryridge") \} \}
```

■ Find the names of all customers who have an account at all branches located in Brooklyn:

```
\{ \langle c \rangle \mid \exists n \ (\langle c, s, n \rangle \in \text{customer}) \land \\ \forall x,y,z (\langle x, y, z \rangle \in \text{branch} \land y = \text{"Brooklyn"}) \Rightarrow \\ \exists a,b (\langle x, y, z \rangle \in \text{account} \land \langle c,a \rangle \in \text{depositor}) \}
```

Database System Concepts

3.85

Safety of Expressions

$$\{ \langle x_1, x_2, ..., x_n \rangle \mid P(x_1, x_2, ..., x_n) \}$$

is safe if all of the following hold:

- 1.All values that appear in tuples of the expression are values from dom(P) (that is, the values appear either in P or in a tuple of a relation mentioned in P).
- 2.For every "there exists" subformula of the form $\exists x (P_1(x))$, the subformula is true if an only if $P_1(x)$ is true for all values x from $dom(P_1)$.
- 3. For every "for all" subformula of the form $\forall_x (P_1(x))$, the subformula is true if and only if $P_1(x)$ is true for all values x from $dom(P_1)$.

Database System Concepts

3.86

End of Chapter 3
